Fluorinated isoflavanones and bifunctionalized isoflavanones were synthesized through a one-step gold(I)-catalyzed annulation reaction. These compounds were evaluated for their in vitro inhibitory activities against aromatase in a fluorescence-based enzymatic assay. Selected compounds were tested for their anti-proliferative effects on human breast cancer cell line MCF-7. Compounds 6-methoxy-3-(pyridin-3-yl)chroman-4-one (3c) and 6-fluoro-3-(pyridin-3-yl)chroman-4-one (3e) were identified as the most potent aromatase inhibitors with IC50 values of 2.5 μM and 0.8 μM. Therefore, these compounds have great potential for the development of pharmaceutical agents against breast cancer.

1. Introduction

Breast cancer is the most common type of cancer found in women worldwide, and it is reported that one in every eight women develops metastatic breast cancer in their lifetime.1 There is a high concentration of estrogen in breast tissue, therefore the risk of developing breast cancer increases greatly.2 In addition, immature breast tissue cells allow stronger binding of carcinogens to breast tissue cells and they possess lower DNA repair capacity. Aromatase is a cytochrome P450 enzyme that has been found to catalyze the last and rate-limiting step of endogenous estrogen synthesis. Chemically, aromatase catalyzes the oxidation and aromatization of androgens (testosterone and androstenedione) to estrogens (estrone and estradiol).3 Aromatase is present in breast tissue and is the source of local estrogen production in breast cancer tissues.4 Since 75% of breast cancer tumors are hormone-dependent, interfering with the production of estrogen using aromatase inhibitors (AIs) is a validated target. In this work, we expand on the types of AIs currently available by reporting for the first time more potent isoflavanone AIs that have not been explored previously.

There are two types of AIs: steroidal (type I inhibitors) and non-steroidal (type II inhibitors), based on their chemical structure.5 Steroidal AIs (e.g., exemestane in Fig. 1) are mechanism-based inhibitors which bind to the enzyme active site irreversibly. On the other hand, many nonsteroidal AIs (e.g., letrozole and anastrozole in Fig. 1) bind to the enzyme’s active site reversibly by non-covalent interactions such as heme iron coordination, hydrogen bonding, etc. Both types of AIs serve to block the aromatase function in order to prevent its estrogen production. AIs have been used in the treatment of hormone-dependent breast cancer and have shown clear superiority compared with the traditional treatment selective estrogen receptor modulators (SERMs) such as tamoxifen.6

Flavonoids have been shown to have antiviral, anti-inflammatory, antimutagenic and anticarcinogenic activities. Some naturally occurring flavones, flavanones and isoflavones have been reported to inhibit aromatase and affect breast cancer cell proliferation. Being a rare class of natural products, the aromatase inhibition effects of isoflavanones were scarcely reported. The aromatase inhibition potencies of flavonoid core structures are summarized...
in Figure 2. It is interesting to note the different activities exhibited by flavone, flavanone and isoflavone. Unlike flavone or flavanone which showed moderate inhibition against aromatase, isoflavone is inactive toward aromatase. In our previous study, we showed for the first time that an isoflavanone-based AI 1a was active against aromatase with an IC_{50} value of 29 µM, probably due to increased hydrophobic interactions between isoflavanone and the aromatase active site. This indicated the potential medicinal value of this subclass of flavonoid compounds.

Fluorinated drugs have been a very popular topic in the field of pharmaceutical science. In the past 50 years, approximately 20% of pharmaceuticals contain one or more fluorine atoms. The rate of introduction of fluorinated drugs has increased compared to past years. Fluorine has effects on several properties of drug molecules including: drug-target interactions and specificity, metabolic stability, acidity or basicity, membrane permeability and toxicity. It has been used as a bioisostere for H, OH and NH₂ groups to modulate bioactivity and the pharmacological properties of medicines. The fluorine atom is highly electronegative and small. The addition of fluorine to an aryl ring or other π-system increases the lipophilicity as a result of electron donation of fluorine lone pair electrons by resonance. The short contacts involving fluorine atoms between proteins and fluorinated ligands are very frequent, and they may increase the fluorinated molecule’s binding affinity for the enzyme. Thus, fluorine has played and will continue its important role in drug design.

To expand on this important new isoflavanone scaffold, we chose to explore fluorinated and bifunctionalized AIs. Herein we report our effort to optimize isoflavanone AIs through structure-activity relationship analysis and enhanced binding interaction design identified via computation. The enzymatic and cell-based assays were used to evaluate the biological activities. Computational docking of the AIs into the aromatase active site was used to determine the crucial interactions that occur within the enzyme pocket. The physicochemical properties such as LogD, number of hydrogen bond donors, number of hydrogen bond acceptors and polar surface area were also calculated to gain some insight into their pharmacokinetic effects. Selected compounds from isoflavonone AIs were tested further for their anti-proliferative effects on human breast cancer cells. The bioactivity and physicochemical properties exhibited by these isoflavonone compounds provide useful information to develop more potent yet less toxic aromatase inhibitors.

2. Results

2.1. Design and synthesis of fluorinated and bifunctionalized isoflavanone compounds

For the beneficial effects of fluorine mentioned above, eight fluorinated isoflavonones 2a–2h were synthesized according to Scheme 1 and evaluated for their biological activities. A microwave-assisted, gold(I)-catalyzed annulation reaction of fluorinated hydroxysteroids and phenylacetylenes was utilized to synthesize these isoflavonones.

Compared to AIs selected drugs, the molecular weights and polar surface areas of the isoflavonone AIs synthesized in our lab were relatively small. For example, the polar surface areas (PSA) for 6-bromo-3-phenylchroman-4-one 1b (PSA = 26.3 Å²), 3-(biphenyl-4-yl)chroman-4-one 1c (PSA = 26.3 Å²), 3-(4-Phenoxypyphenyl)chroman-4-one 1d (PSA = 35.3 Å²) and 3-(pyridin-3-yl)chroman-4-one 1e (PSA = 39.2 Å²) were only about half of that for letrozole (PSA = 78.3 Å²). This provided additional opportunities to modify these AIs with additional functional groups. The development of an aromatase inhibitor with multiple functional groups is an attractive concept as this single agent should inhibit estrogen biosynthesis by binding to the aromatase through two or more of the following interactions: hydrophobic interactions, hydrogen bonding and heme iron coordination. In addition, the extra functional groups can be used to fine tune the physicochemical properties of AIs so that desirable bioavailability and pharmacokinetic properties can be achieved. Therefore, five bifunctionalized isoflavonones 3a–3e were synthesized according to Scheme 1 and tested for their inhibitory effects against aromatase. The structures of fluorinated isoflavonones 2a–2h and bifunctionalized isoflavonones 3a–3e are listed in Table 1.

2.2. Aromatase inhibition activities of fluorinated and biofunctionalized AIs

Aromatase inhibition was determined by using a fluorogenic substrate (7-methoxy-trifluoromethylcoumarin) and human CYP 19 aromatase with ketoconazole as positive control. Each compound was tested in triplicate measurements and the average IC_{50} value can be seen in Table 1. Fluorinated isoflavonone 2b showed stronger inhibitory effects against aromatase compared to the parent molecule 1a while compounds 2c and 2b were inactive. No significant inhibition occurred with bifunctionalized isoflavonones 3a and 3b. Bifunctionalized isoflavonones 3c and 3e showed improved inhibition against aromatase.

Also shown in Table 1 are the calculated important physicochemical properties (partition coefficient between n-octanol and water logP, number of hydrogen bond donors Htot, number of
2.3. Estrogen-dependent MCF-7 growth inhibition

Examination in human breast cancer cells of the synthesized compounds was accomplished. As a starting point, compounds 1b–e were examined for activity in MCF-7 breast cancer cells using letrozole as a positive control. To examine activity, MCF-7 cells were grown under two different conditions. First, as is standard MCF-7 cells were raised in estrogen, low picomole, which has been shown to include both estrogen and estrogen receptor content. With added estrogen the doubling time was twice as fast and stabilized over 10 days. The doubling rate increased more than 2-fold during this period. In contrast, MCF-7 cells raised without estrogen and phenol red displayed an altered phenotype, grew more slowly, and importantly had reduced sensitivity towards anti-estrogen and phenol red.

2.4. Docking poses for isoflavanone AlS

Both enantiomers of synthesized isoflavanones were docked into the aromatase active site (PDB code 3EQM), and the enantio-mer with the higher docking score was used to identify crucial enzyme/inhibitor interactions. The factors which were taken into account in the docking score included external hydrogen bonds, internal torsion and internal van der Waals interactions. The top docking scores for active isoflavanone 2a, 2b, 2g and 3e were 55.2, 53.9, 56.3 and 56.9 kJ/mol. The dominant interactions for 6-fluoroisoflavanone 2a (Fig. 4a) and 3, 5-difluoroisoflavanone 2g (Fig. 4c) predicted by docking poses were π–π stacking interactions between the isoflavanone B ring and the heme group in the enzyme active site. The binding interactions between 8-fluoroisoflavanone 2b (Fig. 4b) and the aromatase active site were more complicated than those of 2a and 2g. At least three different types of interactions were noticed from our study: heme iron coordination, π–π stacking interactions and hydrogen binding. Specifically, the C4 carbonyl of 2b coordinates to the heme iron with a predicted distance of 2.9 Å. Carbonyl-heme iron coordination is common for isoflavanone AlS, and it has been observed for 2-phenyl-2,3-dihydro-[H]-benz[1]chromen-1-one-3-(4-phenoxyphenyl)chroman-4-one and 3-(3,5-dimetoxiyphenyl)chroman-4-one in our previous study. The π–π stacking interactions are frequently involved in binding modes between the ligand and aromatase amino acid residues such as Phe 221, Trp 224 or the heme group. Compound 2b showed π–π stacking interactions with Trp 224 (distance = 3.3 Å). The hydrogen binding interactions between the C7-H of 2b and the enzyme amino acid residue Asp309 (distance = 2.4 Å) were also predicted in the docking study. The bifunctionalized isoflavanone 3e was docked into the enzyme active site and its docking pose is shown in Figure 4d. The crucial interactions between compound 3e and the enzyme active site included the following: first, the coordination between the 3e pyridyl nitrogen and the heme iron atom (distance = 2.5 Å); second, the interaction between the A ring of 3e and the enzyme amino acid residue Arginine 115 (distance = 3.8 Å). The pyridyl nitrogen and heme iron coordination is the most important interaction for heterocyclic isoflavanones as it was also observed in our previous study for compounds such as 3-(pyridin-3-yl)chroman-4-one. Even though the amino acid residue Thr 310 showed ligand exposure in the docking study, there were no obvious hydrogen bonding interactions between the Thr 310 side chain OH and the 3e pyridyl nitrogen.

3. Discussion

3.1. The effect of fluorine on isoflavanone AIs

The addition of fluorine atoms on the isoflavanone scaffold did not improve the calculated physicochemical properties and predicted toxicity profiles significantly when compared with their parent molecule 1a. Among the physicochemical properties listed in Table 1, the most important factor is Log P which measures the solubility and permeability of orally-active drug molecules. A drug-like molecule usually has a Log P value between 0 and 3. Most of the fluorinated isoflavanones had log P values around 3.50 (Table 1), similar to the parent molecule 1a which had a log P value of 3.40, indicating potential poor bioavailability. Thus, the physicochemical properties of these compounds could be further modulated by installing additional polar functional groups. The fluorinated isoflavanone AIs usually exhibited low to medium predicted toxicity profiles. The active fluorinated isoflavanones 2b and 2g were predicted to have low mutagenic, tumorigenic and irritating toxicity profiles (Table 1).

The unique hydrogen binding pattern between the C7-H of 8-fluoroisoflavanone 2b and the enzyme amino acid residue Asp309 indicates the increased acidity of isoflavanone compounds in the presence of fluorine. Namazian reported that fluorine substituents could significantly increase the gas-phase acidity of benzene, which might make the aromatic ring more capable of...
forming hydrogen bonds. Also, it has been noticed that β-fluorination invariably increases C–H acidity due to the stabilization of the carbocation by the inductive effect and hyperconjugative resonance.\textsuperscript{3a,3b} Given these facts and the strong electronegativity of fluoride, the observed hydrogen bonding might result from the increased acidity of C7-H and the close proximity with Asp309.

The active site of aromatase (CPY19) is highly hydrophobic. By the addition of fluoride the binding affinity might increase as seen with the most potent compound 8-fluoroisoflavanone 2b.

The hydrophobic interactions between the B ring of 3’,5’-difluoroisoflavanone 2g and the heme porphyrin (distance = 3.4–3.9 Å, Fig. 4c) increased when compared with compound 2a which has no fluoride on its B ring (distance = 3.5–4.1 Å, Fig. 4a). This can be explained from the effect of fluoride substituents on lipophilicity. Although there might be exceptions, aromatic fluorination or fluorination adjacent to atoms with π bonds usually increases lipophilicity due to the resonance donor nature of fluoride.\textsuperscript{3a}

The effects of fluoride substituents are additive and with each additional fluoride, the compound becomes increasingly lipophilic\textsuperscript{3c} and its LogP value becomes larger. The logP values for non-, mono- and difluorinated isoflavonones 1a, 2a and 2g are 3.40, 3.51 and 3.65, respectively. Therefore, the hydrophobic interactions increased from compound 2a to 2g.

3.2. The effect of bifunctional groups on isoflavonone AIs

The addition of a second functional group serves the following purposes: first, to enhance the enzyme/substrate binding interactions through multiple binding sites; second, to fine-tune the pharmacokinetic and pharmacodynamics properties of potential drug molecules. Methoxyl, phenoxyl, benzo, halogens and pyridyl groups on the isoflavonone scaffold have resulted in favorable interactions with aromatase.\textsuperscript{3f} Since the C6 position is very important for enzymatic bioactivity of isoflavonone AIs, the second functional group was mostly installed at the C6 position.

Compounds 3a and 3b were designed based on the structure-activity relationships of their active precursors. Specifically, we found in our previous study that 4’-PhO, 6-CH\textsubscript{3}O and 5,6-benzo groups significantly improved the aromatase inhibitory potencies of isoflavonane compounds. It was expected that the enzyme/inhibitor binding interactions could be enhanced by bringing the favorable functional groups together. Even though the calculated physicochemical properties of these compounds were not perfect, as seen by the poor LogP values and predicted high mutagenic toxicity in Table 1, the high activity of their precursors in enzyme assays justify the synthesis and evaluation these compounds. Unfortunately, these two compounds lost their activity in the enzyme inhibition assay. This might arise from the increased volumes of compounds 3a and 3b which no longer fit into the enzyme pocket. Being the end product of cholesterol degradation, estrogens are small in size. Correspondingly, the aromatase active pocket is only 400 Å\textsuperscript{3}, considerably smaller compared to other CYP 450 enzymes which normally have an active site of about 530 Å\textsuperscript{2,26}.

The volumes for AI clinical drugs and aromatase natural substrates are in the range of 254.5–285.7 Å\textsuperscript{3}. Compounds 3a and 3b have significantly larger volumes (380.1 and 356.4 Å\textsuperscript{3}, respectively), which might render them too sterically bulky to fit into the aromatase active site. The best docking score for compound 3a was only 40.0 kJ/mol, indicating its poor binding interactions with the enzyme.

A great improvement was achieved when a methoxy group was added to compound 1e to result in compound 3c (Table 1): the LogP value increased from 1.69 to 1.71, the PSA increased from 39.2 to 48.4 Å\textsuperscript{2}, the volume of this molecule increased from 201.1 to 227.6 Å\textsuperscript{3} and the risk of reproductive toxicity was reduced. More importantly, the IC\textsubscript{50} value of bifunctionalized compound 6-methoxy-3-(pyridin-3-yl)chroman-4-one 3c (Table 1) decreased more than 2-fold when compared with its precursor 3-(pyridin-3-yl)chroman-4-one 1e. Encouraged by this discovery and our findings on fluorinated compounds, 8-fluoro-3-(pyridin-3-yl)chroman-4-one 3d and 6-fluoro-3-(pyridin-3-yl)chroman-4-one 3e were prepared and tested for their enzymatic activity. Being the most active compound in this study, isoflavonone 3e (IC\textsubscript{50} = 0.8 µM) showed a 7-fold increase in potency when compared with its precursor 3-(pyridin-3-yl)chroman-4-one 1e (IC\textsubscript{50} = 5.8 µM), and a 36-fold increase in potency when compared with its parent molecule 1a (IC\textsubscript{50} = 29 µM). Coupled with its desirable physicochemical properties, predicted low toxicity profile and the beneficial effects of fluoride, compounds 3d and 3e represented a highly interesting class of potential anti-breast cancer agents.

3.3. Estrogen-dependent MCF-7 growth inhibition

Under physiological conditions, typical estrogen levels are 20–400 pM.\textsuperscript{26} Therefore, the use of a baseline level of estrogen may be more meaningful for the assessment of anti-proliferative activities of isoflavonane AIs. The estrogen used in our cell assays was β-estradiol and the concentration required to stimulate MCF-7 cell proliferation was determined to be 12 pM. Using this concentration, the cytotoxicity of selected isoflavonane AIs was tested against the human breast cancer MCF-7 cell line to estimate their IC\textsubscript{50} values. The investigation of the antiproliferative effect on human breast cancer cells showed interesting cytotoxic activity of some isoflavonone compounds such as 1d, 1e and 3d. For mono-functionalized isoflavonanes, these results are mostly in agreement with their aromatase inhibitory potencies, even though the IC\textsubscript{50} values for their cytotoxic effects are about 2 to 7 times higher than their aromatase inhibitory potencies. For bifunctionalized isoflavonones, the results were more complicated, likely due to the inclusion of more factors in the cell assays and in the substrate structure. The cellular anti-cancer activity of these new AIs may be at least in part due to the aromatase inhibition, though other mechanisms might also be possible.

4. Conclusion

In conclusion, we have described the synthesis and biological evaluation of two subsets of isoflavonane AIs: fluorinated isoflavonanes and bifunctionalized isoflavonanes. Fluorine substituents on the isoflavonane scaffold might enhance the hydrogen bonding, heme iron coordination and/or hydrophobic interactions between aromatase and its inhibitor. The proper choice and installation of a second functional group on the isoflavonane could improve the physicochemical properties and bioactivities of isoflavonane AIs. These new AIs exhibited aromatase inhibition, cellular anti-cancer activity and desirable drug-like properties. Therefore, isoflavonane AIs appear as interesting candidates for future investigation of their effects to reduce cancer cell proliferation in hormone dependent breast cancer.

5. Experimental

5.1. Chemistry

Reagents and solvents were obtained from Aldrich and used without further purification unless otherwise noted. Toluene was freshly distilled from CaH\textsubscript{2} prior to use. The microwave-assisted reactions were conducted on a single-mode Discover System from CEM Corporation. Power cooling was turned off manually during the reaction to ensure that the reaction temperature reached 200 °C. Thin-layer chromatography was performed using precoated silica gel F254 plates (Whatman). Column chromatography
was performed using pre-packed RediSep RF Silica columns on a CombiFlash RF Flash Chromatography system (Teledyne Isco). NMR spectra were obtained on a Joel 500 MHz spectrometer. Chemical shifts were reported in parts per million (ppm) relative to the tetramethylsilane (TMS) signal at 0.00 ppm. Coupling constants, J, were reported in Hertz (Hz). The peak patterns were indicated as follows: s, singlet; d, doublet; t, triplet; dt, doublet of triplet; dd, doublet of doublet; m, multiplet; q, quartet. Analytical reverse-phase HPLC was carried out using a system consisting of a 1525 binary HPLC pump and 2996 photodiode array detector (Waters Corporation, Milford, MA). A Nova-Pak C18 column (4 µm, 3.9 × 150 mm), also from Waters, was used with a mobile phase of methanol and water (60:40, vol/vol.) plus 0.25% acetic acid, flow rate 1.2 mL/min and UV detection wavelength at 250 nm. Control and data acquisition was done using the Empower 2 software (Waters Corporation, Milford, MA). Synthesized compounds were prepared in methanol to make 1.0 mg/mL stock solutions and 10 µL of solution was injected for the HPLC test. The purity of all the compounds was assessed by HPLC at 254 nm. All final compounds were confirmed to be >95% purity by analysis of their peak area. Mass spectra were obtained on a Waters TQD Tandem Quadrupole Mass Spectrometer, and data was collected in electrospray positive mode (ESI+). High resolution mass spectra were recorded on a Micromass Q-TOF 2 or a Thermo Scientific LTQ-FT™ mass spectrometer operating in electrospray (ES) mode. Calculation of important physicochemical properties (log P, number of hydrogen bond donors and acceptors and polar surface area) was performed using Molinspiration Cheminformatics software at URL http://www.molinspiration.com. Prediction of mutagenic, tumorigenic, irritating and reproductive toxicities and drug score was achieved utilizing OSIRIS Property Explorer software at URL http://www.organic-chemistry.org/prog/peo/.

### 5.1. General procedure for isoflavanone synthesis

The microwave-assisted isoflavanone syntheses were conducted on a single-mode Discover System from CEM Corporation. To an oven-dried standard microwave reaction vial (capacity 10 mL) equipped with a stirring bar was added AuCN (0.05 mmol, 0.05 equiv, 11.0 mg), Bu₄P (0.25 mmol, 0.25 equiv, 61.7 µL), aldehyde (1 mmol, 1 equiv), alkyne (3 mmol, 3 equiv) and 1 mL of freshly distilled toluene. The reaction vial was then sealed with a Teflon septum cap, and the sample was subjected to microwave irradiation at a power of 200 W for 10 min (hold time) at 200 °C. After being cooled down, the vial was opened, and the crude mixture was washed directly on silica gel and was purified by Medium Performance Liquid Chromatography eluding with an ethyl acetate/hexanes gradient to afford the desired products.

#### 5.1.1. 6-Fluoro-3-phenylchroman-4-one (2a)

Synthesized from 5-fluorosalicylaldehyde (0.5 mmol, 1 equiv, 80.8 mg) and phenylacetylene (1.5 mmol, 3 equiv, 164.7 µL) according to the general procedure for the synthesis of isoflavanone derivatives described above. Orange yellow solid. Yield: 25.1%. Purity: 98.4%. Rₜ = 0.45 (10% EtOAc/Hex). ¹H NMR (CDCl₃, 500 MHz, ppm): δ 2.76 (s, 3H), 6.97 (d, J = 9.2 Hz, 1H), 7.42 (d, J = 6.4 Hz, 2H), 7.50 (s, 1H), 7.89 (d, J = 8.3 Hz, 1H), 7.91 (d, J = 7.8 Hz, 1H), 8.20 (d, J = 6.4 Hz, 1H). ¹³C NMR (CDCl₃, 125 MHz, ppm): δ 139.2, 129.6, 128.5, 122.6, 121.3, 119.0, 118.0, 108.1, 107.9, 72.2, 52.3. HRMS Calculated for C₁₇H₁₃O₂FNa [M+Na] 265.0641, found 265.0630.

#### 5.1.1.5. 3-(2-Fluorophenyl)chroman-4-one (2d)

Synthesized from 1-ethynyl-2-fluorobenzene (3 mmol, 3 equiv, 314.2 µL) according to the general procedure for the synthesis of isoflavanone derivatives described above. White solid. Yield: 25.1%. Purity: 99.5%. Rₜ = 0.43 (10% EtOAc/Hex). ¹H NMR (CDCl₃, 500 MHz, ppm): δ 2.76 (s, 3H), 6.97 (d, J = 9.2 Hz, 1H), 7.42 (d, J = 6.4 Hz, 2H), 7.50 (s, 1H), 7.89 (d, J = 8.3 Hz, 1H), 7.91 (d, J = 7.8 Hz, 1H), 8.20 (d, J = 6.4 Hz, 1H). ¹³C NMR (CDCl₃, 125 MHz, ppm): δ 139.2, 129.6, 128.5, 122.6, 121.3, 119.0, 118.0, 108.1, 107.9, 72.2, 52.3. HRMS Calculated for C₁₇H₁₃O₂FNa [M+Na] 265.0641, found 265.0630.

#### 5.1.1.6. 3-(3-Fluorophenyl)chroman-4-one (2e)

Synthesized from salicylaldehyde (1 mmol, 1 equiv, 113.3 µL) and salicylaldehyde (3 mmol, 3 equiv, 314.2 µL) according to the general procedure for the synthesis of isoflavanone derivatives described above. Light yellow, flaky solid. Yield: 30.5%. Purity: 96.9%. Rₜ = 0.41 (10% EtOAc/Hex). ¹H NMR (CDCl₃, 500 MHz, ppm): δ 2.76 (s, 3H), 6.97 (d, J = 9.2 Hz, 1H), 7.42 (d, J = 6.4 Hz, 1H), 7.32 (m, 1H), 7.08–7.00 (m, 2H), 4.67 (d, J = 3.6 Hz, 2H), 3.99 (d, J = 3.2 Hz, 1H). ¹³C NMR (CDCl₃, 125 MHz, ppm): δ 191.4, 163.9, 161.5, 137.4, 136.3, 130.4, 127.9, 124.4, 121.9, 120.9, 118.0, 115.8, 115.0, 71.2, 52.0. HRMS Calculated for C₁₇H₁₃O₂FNa [M+Na] 265.0633, found 265.0635.

#### 5.1.1.7. 3-(3,5-Difluorophenyl)chroman-4-one (2g)

Synthesized from 3,5-difluorosalicylaldehyde (0.5 mmol, 1 equiv, 132.6 µL) and 1-ethynyl-2-fluorobenzene (3 mmol, 3 equiv, 340 µL) according to the general procedure for the synthesis of isoflavanone derivatives described above. Yellow solid. Yield: 28.3%. Purity: 98.8%. Rₜ = 0.43 (10% EtOAc/Hex). ¹H NMR (CDCl₃, 500 MHz, ppm): δ 2.76 (s, 3H), 8.31 (d, J = 9.2 Hz, 1H), 7.42 (d, J = 9.2 Hz, 1H), 7.32 (m, 1H), 7.08–7.00 (m, 2H), 4.67 (d, J = 3.6 Hz, 2H), 3.99 (d, J = 3.2 Hz, 1H). ¹³C NMR (CDCl₃, 125 MHz, ppm): δ 191.4, 163.9, 161.5, 137.4, 136.3, 130.4, 127.9, 124.4, 121.9, 120.9, 118.0, 115.8, 115.0, 71.2, 52.0. HRMS Calculated for C₁₇H₁₃O₂FNa [M+Na] 265.0633, found 265.0635.

#### 5.1.1.2. 8-Fluoro-3-phenylchroman-4-one (2b)

Synthesized from 3-fluorosalicylaldehyde (0.5 mmol, 1 equiv, 70.1 mg) and phenylacetylene (1.5 mmol, 3 equiv, 164.7 µL) according to the general procedure for the synthesis of isoflavanone derivatives described above. Orange yellow solid. Yield: 21.5%. Purity: 99.2%. Rₜ = 0.32 (10% EtOAc/Hex). ¹H NMR (CDCl₃, 500 MHz, ppm): δ 7.72 (d, J = 8.3 Hz, 1H), 7.27–7.25 (m, 6H), 6.99–6.95 (m, 1H), 4.76 (d, J = 6.4 Hz, 2H), 4.04 (t, J = 7.1 Hz, 1H), ¹³C NMR (CDCl₃, 125 MHz, ppm): δ 191.2, 150.7, 134.4, 129.1, 128.6, 128.1, 123.1, 122.8, 121.9, 121.8, 121.1, 72.1, 52.3. HRMS Calculated for C₁₇H₁₃O₂FNa [M+Na] 265.0641, found 265.0630.
103.5, 70.8, 51.7. HRMS Calculated for C13H12O2F [M+H] 259.0571, found 259.0568.

5.1.1.8. 3-(4-(Trifluoromethyl)phenyl)chroman-4-one (2h)

Synthesized from salicylaldehyde (1 mmol, 1 equiv, 104.7 μL), and 1-ethyl-4-trifluoromethylbenzene (3 mmol, 3 equiv, 489.4 μL) according to the general procedure for the synthesis of isoflavonane derivatives described above. Light yellow solid. Yield: 19.6%. Purity: 98.5%. Rf = 0.39 (10% EtOAc/Hex).

1H NMR (CDCl3, 500 MHz, ppm): δ 7.95 (d, J = 7.8 Hz, 1H), 7.61 (d, J = 7.8 Hz, 2H), 5.72 (t, J = 8.3 Hz, 1H), 7.41 (d, J = 8.3 Hz, 2H), 7.00–7.08 (m, 2H), 4.68 (d, J = 7.3 Hz, 2H), 4.06 (t, J = 8.0 Hz, 1H). 13C NMR (CDCl3, 125 MHz, ppm): δ 191.4, 161.6, 139.1, 136.5, 129.1, 127.9, 125.9, 121.9, 120.9, 118.0, 71.1, 52.1, 13.6. HRMS Calculated for C13H12O2FNa [M+Na] 351.0609, found 351.0604.

5.1.1.9. 2-(4-Phenoxyphenyl)-2,3-dihydro-1H-benzo[f]chromane-1-one (3a)

Synthesized from 2-hydroxy-1-naphthaldehyde (1 mmol, 1 equiv, 68.9 mg), and 1-ethyl-4-phenoxybenzene (1.2 mmol, 3 equiv, 217 μL) according to the general procedure for the synthesis of isoflavonane derivatives described above. Light yellow solid. Yield: 35.1%. Purity: 98.5%. Rf = 0.39 (10% EtOAc/Hex).

1H NMR (CDCl3, 500 MHz, ppm): δ 0.39 (m, J = 3.2 Hz, 1H), 7.60 (t, J = 8.0 Hz, 1H), 7.25–7.29 (m, 1H), 7.13 (d, J = 8.7, 3.2 Hz, 1H), 7.91 (d, J = 9.2, 7.8 Hz, 2H), 4.59–4.64 (m, 2H), 3.96 (dd, J = 8.2, 5.05 Hz, 1H). 13C NMR (CDCl3, 125 MHz, ppm): δ 193.3, 163.6, 157.0, 137.8, 131.9, 130.3, 129.9, 129.8, 129.6, 126.8, 126.1, 125.0, 123.5, 119.2, 119.0, 118.7, 71.3, 52.3. HRMS Calculated for C26H16O2Na [M+Na] 389.1154, found 389.1140.

5.1.1.10. 6-Methoxy-3-(4-phenoxypyridin-3-yl)chroman-4-one (3c)

Synthesized from 2-hydroxy-5-methoxybenzaldehyde (1 mmol, 1 equiv, 108.1 mg), and 3-ethynylpyridine (3 mmol, 3 equiv, 49.8 mg) according to the general procedure for the synthesis of isoflavanone derivatives described above. Light yellow solid. Yield: 36.3%. Purity: 97.5%. Rf = 0.26 (26.9% EtOAc/Hex).

1H NMR (CDCl3, 500 MHz, ppm): δ 3.54 (s, 3H), 7.25–7.29 (m, 1H), 7.18 (d, J = 8.7, 3.2 Hz, 1H), 7.20–7.12 (m, 2H), 6.94–7.02 (m, 5H), 4.57–4.64 (m, 2H), 3.96 (dd, J = 8.2, 5.05 Hz, 1H), 3.96 (dd, J = 8.2, 5.05 Hz, 1H). 13C NMR (CDCl3, 125 MHz, ppm): δ 192.3, 161.8, 157.8, 157.1, 157.0, 137.8, 131.9, 130.3, 129.9, 129.8, 129.6, 126.8, 126.1, 125.0, 123.5, 119.2, 119.0, 118.7, 71.3, 52.3. HRMS Calculated for C26H16O2FNa [M+Na] 389.1154, found 389.1140.

5.2. Aromatase activity assay

Inhibitory potencies of compounds were determined according to an established procedure using a commercially available aromatase test kit from BD Gentest. This fluorescence-based assay measures the rate at which recombinant human aromatase (baculovirus/insect cell-expressed) converts the substrate 7-methoxy-trifluoromethylcoumarin (MFC) into a fluorescent product 7-ethynyl-trifluoromethylcoumarin (HFC) (λex = 409 nm, λem = 530 nm) in a NADPH regenerating system. Briefly, concentrated stock solutions of test compounds were prepared in acetonitrile. 100 μL samples containing serial dilutions of test compounds (dilution factor of 3 between samples) and cofactor mixture (0.4 μM glucose-6-phosphate dehydrogenase; 16.2 μM NADP; 825 μM MgCl2; 825 μM glucose-6-phosphate; 50 μM citrate buffer, pH 7.5) were prepared in a 96 well plate. After incubating the plate for 10 min at 37 °C, 100 μL of an aromatase/P450 reductase/substrate solution (105 μg protein/mL enzyme; 50 μM MFC; 20 mM phosphate buffer, pH 7.4) were added to each well. The plate was covered and incubated for 30 min at 37 °C. 75 μL of 0.5 M Tris base were then added to stop the reaction and the fluorescence of the formed de-methylated MFC was measured with a plate reader (SpectraMax Gemini, Molecular Devices).

Fluorescence intensities, which were proportional to the amount of reaction product generated by aromatase, were graphed as a function of inhibitor concentration and then fit to a 3-parameter logistic function. Inhibitory potencies were expressed in terms of an IC50 value, the inhibitor concentration necessary to reduce the enzyme activity by half. Each experiment was performed at least in triplicate.

5.3. Molecular modeling

The coordinates of the X-ray crystal structure of the aromatase/androstenedione complex (PDB code 3EQM) were downloaded from the Protein Databank (http://www.rcsb.org) and imported into the modeling program SYBYL (version 8.0; Tripos, St. Louis, MO). All non-protein components were deleted and hydrogen atoms were added to the protein structure. Partial charges were assigned according to the Amber library and the positions of the added hydrogen atoms were optimized by molecular mechanics minimization that kept the positions of the heavy atoms static. The energy minimization was performed with the Powell method in combination with the Amber7 FF99 force field, a distance-dependent dielectric constant of 0, and a convergence criterion of 0.05 kcal/(mol Å). The molecular structures of inhibitors were also prepared in SYBYL and the conformational energy of each structure was minimized by molecular mechanics (MMFF94s force field, MMFF94 charges, and a distance-dependent dielectric constant of 4) using the conjugate gradient method and a termination criterion of 0.01 kcal/(mol Å).

Author's personal copy
Inhibitor structures were computationally docked into the enzyme's binding site using the program GOLD (version 5.0.1; CCDC, Cambridge, UK). GOLD operates with a genetic search algorithm and allows for complete ligand and partial binding site flexibility.29

The scoring function GoldScore was used and the size and center of the docking sphere were as reported before.3 The settings for the genetic algorithm runs were kept at their default values (population size: 100, selection pressure: 1.1; number of operations: 100,000, the number of islands: 5, niche size: 2, probability for migration, mutation, and crossover: 10%, 95%, and 95%, respectively). For each ligand, 30 runs were performed under identical conditions.

5.4. Cell assay

MCF-7 cells were obtained from the NCI-Federick national lab. The cells were cultured at 37 °C in a 5% CO2 humidified atmosphere in RPMI-1640 medium containing 10% FBS, 0.01 mg/ml insulin and 10 nM β-estradiol (Sigma). Assays were accomplished by seeding cells at a density of 15,000 cells/well in a 24 well plate and incubated at 37 °C overnight. Then cells were treated for 72 h with indicated concentrations of freshly dissolved compounds. The medium containing compounds was discarded; fresh medium containing 20 μL of MTT (5 mg/ml) was added to each well and incubated for an additional 4 h. The medium was removed after adding 500 μL of DMSO to each well the optical densities at 570 nm were determined. The IC50 values were calculated using KaleidaGraph (Synergy Software, USA) software.
